ABSTRACT: HSP70 is a molecular chaperone and a key component of the heat-shock response. Because of its proposed importance in oncology, this protein has become a popular target for drug discovery, efforts which have as yet brought little success. This study demonstrates that adenosine-derived HSP70 inhibitors potentially bind to the protein with a novel mechanism of action, the stabilization by desolvation of an intramolecular salt-bridge which induces a conformational change in the protein, leading to high affinity ligands. We also demonstrate that through the application of this mechanism, adenosine-derived HSP70 inhibitors can be optimized in a rational manner.

INTRODUCTION

Heat-shock proteins are a highly conserved family of molecular chaperones that facilitate the folding, stability, and cellular localization of their substrate proteins. Up-regulation of the pathways associated with the heat-shock response has been implicated in a number of disease areas, including cancer. Recent focus has been on the inhibition of the molecular chaperone heat-shock protein 90 (HSP90) using adenosine triphosphate (ATP) competitive inhibitors, an approach that has resulted in considerable success as several compounds have now entered clinical trials. The heat-shock protein 70 (HSP70) family of molecular chaperones represents another potential target for small-molecule mediated antagonism of the heat-shock response pathway. The HSP70 isoform, heat-shock cognate 70 (HSC70), is ubiquitously expressed in tissues, while the inducible isoform, heat-shock protein 72 (HSP72), is largely expressed in response to stress, including treatment with HSP90 inhibitors, and aids cell survival through inhibition of several apoptotic pathways. We have previously shown that dual knockdown of these two HSP70 isoforms in human colon and ovarian tumor cell lines results in apoptosis, which was in contrast with nontumorigenic cell lines where apoptosis was not observed, indicating a potential therapeutic window for HSP70 inhibitors.

To execute their refolding activity, the HSP70 proteins utilize the hydrolysis of ATP to adenosine diphosphate (ADP) and inorganic phosphate (ADP/Pi) in a complex catalytic cycle involving a number of protein conformational changes and through a process which is tightly regulated by various cochaperones such as the heat-shock protein 40 (HSP40) proteins and the nucleotide exchange factor BAG family molecular chaperone regulator 1 (BAG1) protein. While this complexity presents numerous opportunities to antagonize the refolding activity of HSP70, the clearest strategy remains ATP-competitive binding of inhibitors to the conserved nucleotide-binding domain of the protein. Unfortunately, this approach has proven particularly challenging. There remains only one published chemotype which displays ATP-competitive sub-micromolar inhibition of HSP70 and has been shown to be effective in cellular assays, a chemotype derived from adenosine (Figure 1).

The ATPase domain of HSP70 is a member of the actin ATPase family of proteins, a target class which has delivered very little success in the discovery of high affinity ligands. A recent study to assess the potential of the HSP70-ATP binding site for antagonism with small molecules using SiteMap described the target as “difficult”, while a separate analysis using a fragment-based screening approach returned a very low hit rate (0.4%), a result generally associated with low ligandability. Several studies into the biochemical mechanism of HSP70 refolding activity and ATP hydrolysis have demonstrated that the ATP binding site of HSP70 in solution is highly flexible in nature, undergoing numerous conformational changes.

With the challenge of finding ATP-competitive hit matter against HSP70 hindering the potential development of inhibitors for this important target, we sought to investigate...
the binding mechanism of adenosine-derived ligands to the ATP site of HSP70. The aim was to improve our understanding of how high affinity ligands bind to this region of the protein so that this knowledge could be applied to future inhibitor design.

**RESULTS AND DISCUSSION**

**Development of Toyocamycin Derived Ligands.** The slow turnover of ATP by HSP70, and the potent product inhibition by ADP/Pi,27 means that using functional assays is a challenge for the characterization of HSP70 ligand binding. Therefore, we focused on surface plasmon resonance (SPR) as a biophysical method to assess the affinity of ligands. Unfortunately, full-length human HSP72 gave poor SPR data in our hands, displaying erratic and difficult to interpret sensograms. Therefore, the nucleotide-binding domain (NBD) of human HSC70 (HSC70-NBD residues 1–381)18 was used in all SPR experiments. Adenosine 1 is a relatively weak ligand for HSC70-NBD, displaying a pK_D = 3.95 ± 0.01 (K_D = 110 μM, n = 3),21 when measured by SPR, but we decided to use this compound as a starting point for our investigations into the binding mechanisms of this chemotype to the HSP70 proteins.

We began by analyzing the importance of the ribose motif to binding of adenosine-derived ligands to the hydrophilic region of the protein. In contrast, removal of the 5′-hydroxyl groups20 from the sugar motif or changing their relative and absolute stereochemistry resulted in no measurable binding being observed with concentrations up to 1 mM (see Supporting Information). Removal of either the 6-amino group or the 3-nitrogen of the adenine ring also resulted in the loss of all measurable affinity. These results demonstrate the importance of the ribose motif and the adenine amino-pyrimidine motif to binding of adenosine-derived ligands to the hydrophilic region of the protein. In contrast, removal of the 5′-hydroxyl was well tolerated, as compound 2 retained its affinity in the SPR assay with a pK_D = 3.88 ± 0.02 (K_D = 130 μM, n = 3) (Figure 2 and Supporting Information Table 1).21

It has previously been shown by Massey et al. that addition of a primary or secondary amine to the 8-position of adenosine resulted in a significant increase in affinity for these ligands.7 In our hands, 8-aminoadenosine 3 gave a pK_D = 5.16 ± 0.01 (K_D = 7.0 μM, n = 3), a 16-fold increase in affinity when compared to adenosine 1. We decided to investigate this substituent in order to better understand its role in the improved affinity of these compounds (Table 1).

*All results are quoted as the geometric mean ± standard error of the mean (SEM) of three independent experiments unless otherwise stated, pK_D = −log10(K_D(μM) × 10^-6)). All values are quoted to 2 significant figures.

Methyl substitution on the 8-amino group (entry 2) gave ligand 4 and resulted in a 2.5-fold drop in affinity,22 while dimethyl analogue 5 (entry 3) displayed a K_D greater than 1 mM. Replacement of the 8-amino substituent with a methoxy group to give 6 (entry 4) also resulted in a complete loss of activity. This dramatic effect on binding suggested that one of the hydrogens of the 8-amino group was involved in hydrogen bonding. To assess whether an intramolecular hydrogen bond to the 5′-hydroxyl was important for affinity, we removed this group to give 7 (entry 5). However, only a 1.6-fold drop in affinity was observed with analogue 7 when compared with 8-N-methylaminoadenosine 4 (entry 2). These results suggest that an intramolecular hydrogen bond between the 8-amino substituent and the 5′-hydroxyl group cannot rationalize the increased affinity observed with the 8-aminoadenosine series.23

We speculated that the role of the 8-amino substituent as a hydrogen bond donor is through interactions with the cyclic ribose oxygen to stabilize a gauche conformation of adenosine, which facilitates binding by reducing the energy barrier to the initial binding event.24
Finally, we sought to investigate the role of the imidazole ring of adenosine to the binding of these ligands to HSP70 (Table 2).

“All compounds were purchased from the relevant commercial suppliers and used without further purification. All results are quoted as the geometric mean ± SEM of three independent experiments unless otherwise stated, $pK_D = -\log_{10}(K_D(\mu M) \times 10^{-n})$. All values are quoted to 2 significant figures.

We screened three commercially available bacterial natural products, all based on the replacement of the purine of adenosine with a pyrrolopyrimidine scaffold, exchanging the nitrogen at the 7-position with carbon. Comparing this change in scaffold to adenosine 1 (entry 1): the more lipophilic derivative tubercidin 8 (entry 2) displayed a 4-fold improvement in affinity, substitution at the 7-position was well tolerated, with the nitrile derivative toyocamycin 9 (entry 3) displaying comparable affinity to adenosine 1, and the primary amide derivative sangivamycin 10 (entry 4) gave a 35-fold increase in affinity at 3.3 μM.

With knowledge of the increased affinity observed with the pyrrolopyrimidine scaffold in hand, we planned to combine the scaffold hop with the improved affinity previously described for 8-amino substitution of the adenosine scaffold. 8-Amino substitution of tubercidin proved synthetically intractable due to the absence of an electron-withdrawing group at the 7-position, making aromatic substitution at the 8-position challenging. Therefore, we focused our efforts on the synthesis of 8-aminotoyocamycin 12 and 8-aminosangivamycin 13 (Scheme 1).

Tribenzoyl intermediate 11 was prepared in four steps and 20% yield using a previously described procedure. Despite repeated attempts, we were unable to introduce an ammonia equivalent to the 8-position. However, we were successful using methylamine as a nucleophile to give 8-N-methylandolotyocamycin 12, which underwent in situ deprotection of the benzoyl group under the reaction conditions. Treatment of intermediate 11 with basic hydrogen peroxide resulted in hydrolysis of the nitrile group, and subsequent addition of methylamine gave 8-N-methylandolasangivamycin 13 in low yield and moderate purity. 8-N-Methylandolasangivamycin 12 gave a $pK_D = 5.47 ± 0.02 (K_D = 3.3 \mu M, n = 3)$ against HSC70-NBD. This result represented a 27-fold improvement in activity compared to toyocamycin 9 (Table 2, entry 1) and a 5-fold increase in affinity when compared to the corresponding 8-N-methyladenosine 12 (Table 1, entry 2). In contrast, 8-N-methylsangivamycin 13 gave a $pK_D = 4.52 (K_D = 30 \mu M, n = 1)$, which is a 7-fold drop in affinity compared to sangivamycin 10 (Table 2, entry 3). We rationalized this structure–activity relationship (SAR) through the potential effect of the 7-substituent on the hydrogen bonding ability of the key 8-N-methylamino group. The primary amide substituent of 13 can form an intramolecular hydrogen bond with the 8-N-methylamino group to give a resonance stabilized six-membered intramolecular hydrogen bond, which would mask the hydrogen bond donor effect of the 8-N-methylamino substituent and block the binding of this ligand.

To develop the toyocamycin scaffold further, we sought to introduce a benzylic substituent to the 8-position amine. Previously, Massey et al. have shown that N-benzyl substitution at the 8-amino position could improve the affinity of adenosine derived inhibitors of HSP70 (Figure 1). Because our toyocamycin derived scaffold 12 had displayed a 5-fold improvement in affinity compared to the corresponding adenosine scaffold 4, we hypothesized that addition of an 8-N-benzyl substituent to toyocamycin would result in an improved chemeotype for HSP70 inhibition. 8-N-Benzyltoyocamycin 14 was prepared via a similar method to 12 using benzylamine as a nucleophile. For comparison, 8-N-Benzyladenosine 15 was prepared in one step via a literature procedure from commercially available 8-bromoadenosine (Scheme 2).

8-N-Benzyladenosine derivative 15 gave a $pK_D = 5.84 ± 0.02 (K_D = 1.5 \mu M, n = 3)$, representing a 12-fold improvement in binding affinity compared to the 8-N-methyladenosine analogue 4 (Table 1, entry 2); however, the 8-N-benzyltoyocamycin analogue 14 gave a $pK_D = 5.56 ± 0.02 (K_D = 2.8 \mu M, n = 3)$, representing little change in affinity compared to 8-N-methyltoyocamycin derivative 12 despite the increase in molecular weight and lipophilicity. Even though toyocamycin 9 was apparently an improved scaffold, when compared to adenosine, for the inhibition of HSP70, we had been unable to develop the compounds beyond a micromolar affinity ligand. We believed that improving our understanding of the complex SAR surrounding the nucleoside core and lipophilic 8-N-benzyl substituent through analysis of ligand/HSP70 co-crystal structures would be crucial to the discovery and development of small-molecule inhibitors of HSP70.

HSP70 Conformations. In 1995, kinetic studies by McKay and Ha using changes in tryptophan fluorescence indicated that the HSP70 isoform, HSC70, undergoes a number of conforma-
tional changes during its catalytic cycle.32 The energy released from ATP hydrolysis drives subsequent conformational changes in the substrate binding domain, allowing HSP70 to carry out its refolding function on client proteins. However, McKay and Ha discovered that ATP and ADP have two distinct binding mechanisms. While ADP binds and then dissociates in an apparent single-step mechanism with slow-off kinetics, the binding of ATP is a two-step process, requiring an additional conformational change of the nucleotide-binding domain prior to ATP hydrolysis. Because it had been demonstrated that the two nucleotide substrates of HSP70 can jump between binding mechanisms, we hypothesized that the complexity surrounding the apparent SAR of the nucleoside derived HSP70 inhibitors was due to a change in mechanism between a one-step and an induced conformational change two-step mechanism, even if kinetically this would be difficult to observe.33

To investigate whether a two-step binding model is consistent with the observed nucleoside SAR, we decided to probe HSP70 ligand binding by X-ray crystallography. There is currently no crystal structure of full-length human HSP70; therefore, we focused our crystallography efforts on the NBD of the human HSP70 isoform HSP72 (HSP72-NBD).

In our hands, ADP 16 gave an affinity of pK_D = 6.49 (K_D = 0.32 μM, n = 1) when measured by SPR against the HSC70-NBD.34 The co-crystal structure of ADP/P_i bound to the HSP72-NBD has previously been solved16a and analysis of this structure clearly revealed a closed conformation of the protein. The two α-helices flanking the sides of the ATP binding site, closed around the adenosine motif of ADP, forming multiple hydrogen bonds with the ribose and adenine moieties of ADP (Figure 3).

From analysis of this structure, the two phosphate groups of ADP form multiple hydrogen bonds within the phosphate binding region of the HSP72-NBD. It is also clear that the HSP72-NBD would need to undergo a conformational change in order for ADP/P_i to dissociate, resulting in the previously described slow-off kinetics.32 It has been suggested previously that the closed conformation is apparently stabilized by the formation of a solvent exposed salt-bridge between lysine-56 and glutamic acid-268.35 Intrigued by the formation of this intramolecular interaction, we then sought to generate a co-crystal structure with the bacterial natural product sangivamycin 10 (K_D = 3.3 μM) (Figure 4).

The crystal structure of sangivamycin 10 revealed a similar hydrogen bonding framework to the adenosine motif of the ADP/P_i structure (Figure 3). The pyrrolopyrimidine ring interacts with serine-275 and the 2’- and 3’-hydroxyls of the ribose interact with lysine-271. However, in contrast to the ADP/P_i HSP72-NBD structure, sangivamycin 10 co-crystallized in a more open conformation. The two α-helices of the nucleotide binding domain are no longer in close proximity, and the solvent exposed salt-bridge between glutamic acid-268 and lysine-56 is absent. It is this difference in the HSP70-NBD conformation which we hypothesize is an important factor in the complexity of SAR observed for nucleoside-derived inhibitors. The binding of both ADP/P_i and sangivamycin 10 are dominated by the formation of multiple hydrogen bonds to key residues in the nucleoside binding cleft but the crucial difference between the two ligands is their ability to induce and stabilize the closed conformation of the HSP72-NBD. It is this...
ligand-driven induced conformational change that leads to high affinity for HSP70. The HSP72-NBD closed conformation observed in the ADP/P, bound structure is presumably brought about by the interactions of the β-phosphate group with the two glycine-rich loops of the phosphate binding region. We speculated that this conformational change could force water molecules from the nucleotide binding domain cleft, strengthening the many hydrogen bond contacts surrounding the adenosine due to the more hydrophobic environment. The absence of the phosphate groups, and in particular the β-phosphate group, in sangivamycin 10 means there is no induced conformational change so the affinity is only dependent on the multiple hydrogen bonds (Figure 5).

Figure 5. Induced open and induced closed conformations of HSP72. PDB 3ATU and 5AQZ, the copper-colored structure represents the co-crystal structure of ADP/P, bound to the HSP72-NBD in the induced closed conformation due to interactions of the phosphate groups through hydrogen bonds with the glycine rich loops and stabilized by the salt-bridge. The gray-colored structure represents the co-crystal structure of sangivamycin 10 bound to the HSP72-NBD. The overlay shows sangivamycin 10 bound to a more open NBD conformation, in which the formation of the Glu-Lys salt-bridge is not possible. Only selected residues are shown and solvent has been omitted for clarity.

An Alternative Approach to Inducing the Closed Conformation of HSP70. Mimicking phosphate groups with druglike ligands represents a significant challenge in medicinal chemistry. However, if it were possible to induce the closed conformation of the HSP70 nucleotide binding domain via an alternative mechanism, then mimicking the β-phosphate would be unnecessary. Because the solvent exposed salt-bridge between glutamic acid-268 and lysine-56 was the only additional enthalpic intradomain interaction that we observed in the HSP70-NBD closed conformation structure, when compared with the more open sangivamycin 10 structure, we hypothesized that a ligand stabilizing this interaction would stabilize the closed conformation of HSP70, leading to increased affinity. We therefore proposed that the previously described potent 8-N-benzyladenosine derived ligands were able induce a conformational change in HSP70 but via a lipophilic mechanism, which would be more amenable to drug discovery. To investigate this hypothesis, we synthesized the known quinoline derived HSP70 inhibitor 17 in one step and 68% yield using our previously described method (Scheme 3).

Scheme 3. Synthesis of Quinoline Adenosine Derivative

Although several 8-N-substituted HSP70 inhibitors have been described in the literature, the 8-N-quinoline adenosine derived ligand 17 was chosen because it was reported to be the highest affinity ligand which was only substituted at the 8-position. In our hands, 17 gave a pKᵦ = 6.14 ± 0.01 (Kᵦ = 0.72 μM, n = 3) against HSC70-NBD when measured by SPR, which was consistent with the data reported in the literature. 8-N-Quinoline aminoadenosine derived ligand 17 was then submitted to our co-crystallization protocol with HSP72-NBD (Figure 6).

Figure 6. Co-crystallization of 8-N-quinoline aminoadenosine derived ligand 17 bound to HSP72. PDB 5AR0, the HSP72 structure clearly demonstrates the formation the key salt-bridge when co-crystallized with 8-N-quinolineadenosine 17. Important hydrogen bonding interactions are indicated with their distances in Å. Only selected residues are shown and solvent has been omitted for clarity.

Co-crystallization of 17 with the HSP72-NBD showed the NBD in a closed conformation (Figure 5), nearly identical to the conformation of the HSP72-NBD in the ADP/Pi 16-bound structures (Figure 6). To our knowledge, this is the first example of a co-crystal structure demonstrating a non-nucleotide ligand binding to the closed conformation of HSP70. The similarity of the respective HSP72 conformations is consistent with a potential role of the induced conformational change in enhancing the affinity of the 8-N-benzyl nucleoside derived HSP70 ligands. However, the mechanism by which the inhibitor induced conformational change occurs must be distinctly different from the mechanism of NBD closure upon nucleotide binding because the quinoline moiety of 17 forms no interactions within the phosphate binding region.

To rationalize the induced conformational change observed with 17, we further analyzed the closed structure of HSP72-NBD to identify the key binding interactions. 8-N-Quinoline adenosine 17 displays a similar hydrogen bonding network with...
the same key residues observed in both ADP/P, and sangivamycin 10, with an additional solvent exposed water molecule bound to the quinoline nitrogen. However, in contrast with the more open conformation observed in the HSP72-NBD sangivamycin 10 complex, the key salt-bridge between glutamic acid-268 and lysine-56, which is present in the nucleotide-bound HSP70-NBD structures, is clearly formed in the 17-bound HSP72-NBD structure (Figure 5). In the ADP/P/ HSC70-NBD co-crystal structure, the salt-bridge is solvent exposed, weakening its effect (Figure 7).38 By contrast, influence of restricting the conformational freedom of the protein, it must be stabilized by the ligand. ADP can achieve this through interactions with the phosphate binding region, while quinoline ligand 17 stabilizes the key salt-bridge through hydrophobic desolvation. Sangivamycin 10 has neither of these substituents so predominately binds to the open conformation.

**Optimizing the 8-Position.** To test this hypothesis, and to generate more active ligands of HSP70 for further development, we synthesized a series of 8-N-benzylaminoadenosine analogues using our previously described method (Table 3).

The 8-N-benzyl derivative 15, as shown previously, gave a pK_D = 5.84 ± 0.02 (K_D = 1.4 μM, n = 3) when measured by SPR against HSC70-NBD. The weaker activity observed with the benzyl group 15 compared to quinoline 17 we rationalized was due to its less efficient desolvation of the glutamic acid/lysine salt bridge by the smaller lipophilic group. Therefore, we decided to add a number of lipophilic substituents to assess whether we could improve the desolvation effect, promote the induced closed conformation, and improve the affinity of the ligands. para-Chloro-substitution gave adenosine derivative 18 (entry 3) with a pK_D = 6.55 ± 0.01 (K_D = 0.28 μM, n = 9), a 5-fold improvement in affinity compared to compound 15 and a 60-fold improvement compared to 8-N-methylaminoadenosine 4 (Table 1, entry 2). Although the kinetics of the these ligands binding to HSP70 were at the limit of what could be accurately measured by SPR, analysis of the off-rate did reveal that the quinoline ligand 17 and the para-chlorobenzyl derivative 18 possessed measurably slow off-rates compared to sangivamycin 10, whose half-life was too short to be observed with this technique (see Supporting Information for details).41 Similar improvements were also observed for the para-fluoro derivative 19 (entry 4, pK_D = 6.34 ± 0.01, K_D = 0.46 μM, n = 3) and para-methyl derivative 20 (entry 5, pK_D = 6.53 ± 0.01, K_D = 0.30 μM, n = 3). Because the crystal structure of this ligand class shows that the benzyl moiety resides in the cleft formed by the two α-helices in the nucleotide binding domain of HSP70, it is unlikely that the para-lipophilic substituents interact with HSP70 via a lipophilic pocket, as the group is essentially solvent exposed. This effect could not be explained by an increase in the overall lipophilicity of the ligand to exploit the nonspecific hydrophobic effect because dichlorobenzyl derivative 21 (entry 6, pK_D = 5.45 ± 0.01, K_D = 3.5 μM, n = 3) displayed a significant drop in affinity.

**CONCLUSIONS**

The ATP binding site of HSP70 is a challenging region of the protein to target with small molecules due to its hydrophilic nature and high flexibility. To target the nucleotide binding domain it is important to understand the conformational changes that this region of the protein undergoes. Using protein/ligand X-ray crystallography, we have demonstrated

**Figure 7.** Overlay of ADP/P, and 8-N-quinoline adenosine 17 co-crystal structures with HSP72. PDB 3ATU and 5AR0, overlay of the ADP/P-HSP72 co-crystal structure (copper) and the 8-N-quinoline adenosine 17-HSP72 co-crystal structure (gray). Only selected residues are shown and solvent has been omitted for clarity.
that non-nucleotide ligands of HSP70 can induce conformational changes in the protein and that these changes can play an important role in the binding of HSP70 inhibitors. In solution, kinetic studies suggest that this protein undergoes a number of conformational changes of not just the nucleotide binding domain but also the substrate-binding domain. Also, interactions between these two domains and the role of cochaperones in these conformational changes have yet to be addressed. Better understanding of the flexibility of HSP70 and its effect on the affinity of ligands will contribute to better assay design and more efficient inhibitor optimization.

### EXPERIMENTAL SECTION

**Experimental Procedures (Chemistry).** Unless otherwise stated, reactions were conducted in oven-dried glassware under an atmosphere of nitrogen using anhydrous solvents. All commercially obtained reagents and solvents were used as received. Thin layer chromatography (TLC) was performed on precoated aluminum sheets of silica (60 F254 nm, Merck) and visualized using short-wave UV light. Flash column chromatography was carried out on Merck silica gel 60 (partial size 40–63 μm). 1H NMR spectra were recorded on Bruker AMX500 (500 MHz) spectrometers using an internal deuterium lock. Chemical shifts are quoted to 0.01 ppm, unless greater accuracy was required, using the following internal references: CDCl3 (δ H 7.26), MeOD (δ H 3.31), and DMSO-d6 (δ H 2.50). Signal multiplicities are recorded as singlet (s), doublet (d), triplet (t), quartet (q), multiplet (m), doublet of doublets (dd), doublet of doublet of doublets (ddd), apparent triplet (app t) broad (br), or obscured multiplet (obs m). Coupling constants, J, are measured to the nearest 0.1 Hz. 13C NMR spectra were recorded on Bruker AMX500 spectrometers at 126 MHz using an internal deuterium lock. Chemical shifts are quoted to 0.01 ppm.

**EXPERIMENTAL SECTION**

To a solution of 8-bromoadenosine (0.11 g, 0.33 mmol) in MeOH (4 mL) was added NaOMe (0.18 g, 3.3 mmol), and the mixture was stirred at room temperature for ~12 h. After this time, the solvent was removed under reduced pressure and the resulting residue was purified by silica gel chromatography eluting with 2 M MeOH/NH3:EtOAc (9:1) to give the desired product as a yellow oil (0.025 g, 26%). 6H (500 MHz, MeOD), 8.06 (s, 1H), 5.91 (d, J = 7.1 Hz, 1H), 4.93 (dd, J = 7.0, 5.2 Hz, 1H), 4.33 (dd, J = 5.2, 2.0 Hz, 1H), 4.21 (s, 3H), 4.16–4.09 (m, 1H), 3.86 (dd, J = 12.6, 2.5 Hz, 1H), 3.71 (dd, J = 12.6, 2.9 Hz, 1H); δC (126 MHz, MeOD) 155.19, 154.01, 150.10, 148.34, 115.35, 87.65, 86.82, 72.43, 71.55, 62.62, 56.69. HRMS (ESI) C12H12N2O2 (M + H+) requires 191.1142, found 191.1152.

**EXPERIMENTAL SECTION**

To a solution of 5-deoxyadenosine (0.024 g, 0.06 mmol) in dioxane (0.5 mL) was added KHPO4 (0.065 g, 0.29 mmol) and bromine (0.023 g, 0.14 mmol) as a solution in water (0.4 mL), and the mixture was stirred at room temperature for 12 h. After this time, the resulting solution was used in the next step without further purification. The product from the previous step (0.032 g, 0.09 mmol) was dissolved in 2 M MeNH2 in EtOH (1.9 mL), and the mixture was heated to 70 °C for ~12 h. After this time, the mixture was cooled to room temperature and the solvent removed under reduced pressure.

The resulting residue was purified by silica gel chromatography eluting with 2 M MeOH/NH3:EtOAc (9:1) to give the desired product as a white solid (0.027 g, 47%); δH (500 MHz, MeOD), 157.19, 153.92, 149.92, 149.22, 116.86, 89.06, 86.97, 71.96, 71.79, 62.86, 41.89. HRMS (ESI) C12H12N2O2 (M + H+) requires 211.1342, found 211.1344.

**EXPERIMENTAL SECTION**

To a solution of 5-deoxyadenosine (0.024 g, 0.06 mmol) in water (0.5 mL) was added KHPO4 (0.038 g, 0.18 mmol) and bromine (0.014 g, 0.08 mmol) as a solution in water (0.4 mL), and the mixture was stirred at room temperature for 12 h. After this time, the resulting solution was used in the next step without further purification. The product from the previous step (0.032 g, 0.09 mmol) was dissolved in 2 M MeNH2 in EtOH (1.9 mL), and the mixture was heated to 70 °C for ~12 h. After this time, the mixture was cooled to room temperature and the solvent removed under reduced pressure.

The resulting residue was purified by silica gel chromatography eluting with 2 M MeOH/NH3:EtOAc (9:1) to give the desired product as a white solid (0.031 g, 71%); δH (500 MHz, MeOD), 155.19, 154.01, 150.10, 148.34, 115.35, 87.65, 86.82, 72.43, 71.55, 62.62, 56.69. HRMS (ESI) C12H12N2O2 (M + H+) requires 211.1346, found 211.1352.

**EXPERIMENTAL SECTION**

To a solution of 5-deoxyadenosine (0.024 g, 0.06 mmol) in water (0.5 mL) was added KHPO4 (0.065 g, 0.29 mmol) and bromine (0.024 g, 0.096 mmol) as a solution in water (0.4 mL), and the mixture was stirred at room temperature for 12 h. After this time, the resulting solution was used in the next step without further purification. The product from the previous step (0.032 g, 0.09 mmol) was dissolved in 2 M MeNH2 in EtOH (1.9 mL), and the mixture was heated to 70 °C for ~12 h. After this time, the mixture was cooled to room temperature and the solvent removed under reduced pressure.

The resulting residue was purified by silica gel chromatography eluting with 2 M MeOH/NH3:EtOAc (9:1) to give the desired product as a white solid (0.031 g, 71%); δH (500 MHz, MeOD), 155.19, 154.01, 150.10, 148.34, 115.35, 87.65, 86.82, 72.43, 71.55, 62.62, 56.69. HRMS (ESI) C12H12N2O2 (M + H+) requires 211.1346, found 211.1352.

**EXPERIMENTAL SECTION**

To a solution of 5-deoxyadenosine (0.024 g, 0.06 mmol) in water (0.5 mL) was added KHPO4 (0.038 g, 0.18 mmol) and bromine (0.014 g, 0.08 mmol) as a solution in water (0.4 mL), and the mixture was stirred at room temperature for 12 h. After this time, the resulting solution was used in the next step without further purification. The product from the previous step (0.032 g, 0.09 mmol) was dissolved in 2 M MeNH2 in EtOH (1.9 mL), and the mixture was heated to 70 °C for ~12 h. After this time, the mixture was cooled to room temperature and the solvent removed under reduced pressure.

HRMS (ESI) C12H12N2O2 (M + H+) requires 211.1346, found 211.1352.
C13H19N6O5 (M + H+) requires 339.1411, found 339.1408.

(126 MHz, MeOD) 35.35, 62.23, 71.62, 72.28, 86.70, 87.49, 98.51, 101.02, 146.72, 147.31, 150.61, 157.70, 160.71. HRMS (ESI) C13H19N6O5 (M + H+) requires 339.1411, found 339.1408.

4-Amino-6-(benzylamino)-7H-(1,2,3,4-tetrahydropyrimidin-2-yl)pyrrolo[2,3-d]pyrimidine-5-carbonitrile 14. (2R,3R,4S,5R)-2-(4-Amino-6-bromo-5-cyano-7H-pyrrolo[2,3-d]pyrimidin-7-yl)-5-(benzoxyl)methyl-tetrahydrofuran-3,4-diol 15. To a solution of 8-bromoadenosine (0.061 g, 0.18 mmol) in 9-yl)-5-(hydroxymethyl)tetrahydrofuran-3,4-diol 19. To a solution of 8-bromoadenosine (0.048 g, 0.14 mmol) in n-butanol (1.4 mL) was added (4-fluorobenzyl)amino)methyl-1774 (2R,3R,4S,5R)-2-(6-Amino-8-((4-methylbenzyl)amino)-9H-purin-9-yl)-5-(hydroxymethyl)tetrahydrofuran-3,4-diol. To a solution of 8-bromoadenosine (0.092 g, 0.53 mmol), and benzylamine (0.038 mL, 0.23 mmol), 1C6H4N3O (M+H+) requires 407.1229, found 407.1376.

(2R,3R,4S,5R)-2-(6-Amino-8-(4-fluorobenzyl)amino)-9H-purin-9-yl)-5-(hydroxymethyl)tetrahydrofuran-3,4-diol 19. To a solution of 8-bromoadenosine (0.048 g, 0.14 mmol) in n-butanol (1.4 mL) was added (4-fluorobenzyl)amino)methyl-1774 (2R,3R,4S,5R)-2-(6-Amino-8-((4-methylbenzyl)amino)-9H-purin-9-yl)-5-(hydroxymethyl)tetrahydrofuran-3,4-diol. To a solution of 8-bromoadenosine (0.092 g, 0.53 mmol), and benzylamine (0.038 mL, 0.23 mmol), 1C6H4N3O (M+H+) requires 407.1229, found 407.1376.

(2R,3R,4S,5R)-2-(6-Amino-8-(4-fluorobenzyl)amino)-9H-purin-9-yl)-5-(hydroxymethyl)tetrahydrofuran-3,4-diol 19. To a solution of 8-bromoadenosine (0.048 g, 0.14 mmol) in n-butanol (1.4 mL) was added (4-fluorobenzyl)amino)methyl-1774 (2R,3R,4S,5R)-2-(6-Amino-8-((4-methylbenzyl)amino)-9H-purin-9-yl)-5-(hydroxymethyl)tetrahydrofuran-3,4-diol. To a solution of 8-bromoadenosine (0.092 g, 0.53 mmol), and benzylamine (0.038 mL, 0.23 mmol), 1C6H4N3O (M+H+) requires 407.1229, found 407.1376.

(2R,3R,4S,5R)-2-(6-Amino-8-(4-fluorobenzyl)amino)-9H-purin-9-yl)-5-(hydroxymethyl)tetrahydrofuran-3,4-diol 19. To a solution of 8-bromoadenosine (0.048 g, 0.14 mmol) in n-butanol (1.4 mL) was added (4-fluorobenzyl)amino)methyl-1774 (2R,3R,4S,5R)-2-(6-Amino-8-((4-methylbenzyl)amino)-9H-purin-9-yl)-5-(hydroxymethyl)tetrahydrofuran-3,4-diol. To a solution of 8-bromoadenosine (0.092 g, 0.53 mmol), and benzylamine (0.038 mL, 0.23 mmol), 1C6H4N3O (M+H+) requires 407.1229, found 407.1376.
MH2, DMSO-δ6 7.90 (s, 1H), 7.70−7.53 (m, 3H), 7.37 (dd, J = 8.3, 2.0 Hz, 1H), 6.55 (s, 2H), 5.99−5.85 (m, 2H), 5.32 (dd, J = 6.6 Hz, 1H, S). 5.18 (J = 4.0 Hz, 1H, S). 4.72 (td, J = 7.0, 5.3 Hz, 1H, S). 4.56 (J = 6.0 Hz, 2H). 4.12 (ddd, J = 5.5, 3.9, 1.9 Hz, 1H, J = 3.2 Hz, 1H), 3.62 (dt, J = 7.0, 3.2 Hz, 2H) 3.45−3.35 (obs. m, 1H). δC (126 MHz, DMSO-δ6) 153.03, 151.44, 150.25, 149.17, 141.70, 131.27, 130.86, 129.66, 129.58, 128.05, 117.38, 88.07, 88.30, 71.53, 71.38, 62.23, 44.76. HRMS (ESI) C17H19Cl2N6O4 (M + H +) requires 425.1544, found 425.1540.

The HSPA1A (HSP72) gene was amplified from the IMAGE clone 3345864 (accession no. BC002453) by PCR using the respective forward and reverse primers 5′-GATGCGACCATGTGGCAAGCGCGGCGGGA-3′ and 5′-ACAGAATCTCTTAATCCTC-3′. The HSP72A gene was cloned into a pTWOE vector, which was modified version of pET17b (Merck Chemicals Ltd., Nottingham, UK) encoding a N-terminal 6xHis-tag followed by a human rhinovirus 3C protease cleavage site. BL21-AI cells (Invitrogen, Paisley, UK) transformed with the vector containing the HSPA1A gene were grown inuria–Bertani medium to an optical density at 600 nm of 0.6 and induced with 0.5 mM isopropyl-β-D-thiogalactopyranoside and 0.2% (w/v) arabinose at 16 h at 20 °C. Cells were harvested by centrifugation at 6000 rpm for 40 min at 4 °C using an Avanti centrifuge J-26XP (Beckman Coulter, High Wycombe, UK) with a JLA 8.100 rotor. Cell pellets were resuspended in 3 volumes of lysing buffer consisting of 25 mM Tris, 50 mM NaCl, 5% (v/v) glycerol, 1x Complete EDTA-free protease inhibitors (Roche, Basel, Switzerland), 25 mM benzonal nuclelease (Merck Chemicals Ltd.) at pH 7.5. Cell lysis was performed by sonication using a Vibra-cell VCX500 (Sonics & Materials Inc., Newtown, CT, USA) with a 13 mm solid probe for 24 cycles of 5 s on, 5 s off with amplitude set at 50%. The lysate was clarified by centrifugation at 20000 rpm for 30 min at 4 °C using an Avanti centrifuge J-26XP (Beckman Coulter) with a JA 25.50 rotor.

The supernatant was passed through a 1.2 μm syringe filter (Sartorius Stedim, Germany) and loaded onto a 5 ml Histap FF column (GE Healthcare, Chalfont St. Giles, UK) equilibrated in buffer A, comprising 25 mM Tris, 50 mM NaCl, pH 7.5, and eluted with a gradient of 0−100% buffer B (buffer A + 250 mM imidazole) over 10 column volumes (CV). Fractions containing HSP72 were pooled, concentrated, and loaded onto a Superdex 200 (16/60) size exclusion column (GE Healthcare) equilibrated in 25 mM Tris, 400 mM NaCl, 2 mM EDTA 5% (v/v) glycerol, pH 7.5, for further purification. Fractions containing HSP72 were pooled and further purified to remove contaminating nucleotides using a 6 ml Resource Q column (GE Healthcare) equilibrated in 20 mM Tris, 2 mM EDTA, 5% (v/v) glycerol, pH 7.5. Following a 10 CV wash with the same buffer, HSP72 was eluted using a gradient from 0 to 500 mM NaCl over 6 CV and loaded onto a Superdex 200 16/60 column (GE Healthcare) equilibrated in a buffer containing 25 mM Tris, 400 mM NaCl, 15 mM EDTA, 5% (v/v) glycerol, pH 7.5. The removal of contaminating nucleotides was followed by measuring the ratio of absorbance at 260 and 280 nm (A260/A280) using a NanoDrop ND-1000 UV spectrophotometer (ThermoFisher, Wilmington, DE, USA).

Samples with A260/A280 below 0.6 were regarded as nucleotide free.

**Experimental Procedure (X-ray Crystallography).** Purified HSP72-NBD protein was thawed; buffer exchanged into fresh 100 mM HEPES pH 7.5 and incubated with 5 mM of the inhibitor for 30 min on ice prior to crystallization. HSP72-NBD/inhibitor co-crystals were grown at 18 °C in sitting drops by mixing equal volumes of protein solution (5−12 mg/mL) and precipitant solution containing 17−28% (v/v) PEG3350, 0.1 M HEPES pH 7.5, 2 mM MgCl2, and 2 mM NaH2PO4. Co-crystals of approximate dimensions 100 × 100 × 300 μm typically formed overnight. Crystals were in liquid nitrogen, using 22.5% (v/v) ethylene glycol for the co-crystals with sangivamycin 10 and 25% (v/v) glycerol for compound 17.

X-ray diffraction data were collected at 100 K at Diamond Light Source (Oxfordshire, UK; beamlines 10−1 and 124). Data were integrated with XDS. All data were imported to MTZ format with POINTLESS, then scaled and merged with AIMLESS and the CCP4 suite.

The structures were solved by molecular replacement with Phaser, with the public domain HSPP72-NBD structure 1S3X as the search model after removal of all nonprotein atoms. Structures were refined in iterative cycles of model building with Coot and refinement with BUSTER. TLS groups were selected with PHENIX phenix.find.tls groups. Ligand restraints were generated with GRADE and MOGUL. The final structure quality was checked with MOLPROBITY. The data collection and refinement statistics are presented in Supporting Information Table S15, and for Fc − Fc′
electron density figures for all structural data, see Supporting Information Figure S14. $F_o - F_c$ electron density figures were generated with CCP4MG.
