35

36 **Translational Relevance (149 words)**

37 Multiple myeloma(MM) is the second commonest haematological malignancy and
38 remains incurable. Beyond tumour biology and genomic features driving disease
39 resistance, host factors including impaired immunity and frailty also contribute to
40 poor outcomes. Despite reports of immune dysfunction in this cancer, clear evidence
41 for the contribution to clinical outcomes remains lacking.

42 We show, for the first time, that high abundance of Treg and PD-1+CD4 effector cells
43 in bone marrow of newly diagnosed patients are independent predictors of early
44 relapse. This work supports growing literature on the importance of CD4 effector
45 cells in MM, and confirms a role for the PD-1/PD-L1 axis to MM pathobiology.

46 Our work identifies Tregs and PD-1+CD4 effectors as potential therapeutic targets,
47 and opens up avenues for further mechanistic studies into early relapse. Pending
48 confirmation in future patient cohorts, such immune parameters may refine existing
49 risk models, facilitating patient stratification for therapeutic strategies targeting key
50 CD4 populations.

51

52

53

54

55 **Abstract (250)**

56

57 **Purpose:** Immune dysregulation is described in multiple myeloma(MM). While
58 preclinical models suggest a role for altered T cell immunity in disease progression,
59 the contribution of immune dysfunction to clinical outcomes remains unclear. We
60 aimed to characterise marrow infiltrating T cells in newly diagnosed patients and
61 explore associations with outcomes of first line therapy.

62 **Experimental Design:** We undertook detailed characterisation of T cells from bone
63 marrow(BM) samples, focusing on immune checkpoints and features of immune
64 dysfunction, correlating with clinical features and progression free survival.

65 **Results:** We found that patients with MM had greater abundance of BM regulatory T
66 cells (Tregs) which, in turn, expressed higher levels of the activation marker CD25
67 compared to healthy donors. Patients with a higher frequencies of Tregs (Treg^{hi}) had
68 shorter PFS, and a distinct Treg immune checkpoint profile (increased PD-1, LAG-3)
69 compared to Treg^{lo} patients. Analysis of CD4 and CD8 effectors revealed that low
70 CD4effector:Treg ratio, and increased frequency of PD-1 expressing CD4^{eff} cells
71 were independent predictors of early relapse over and above conventional risk
72 factors such as genetic risk and depth of response. Ex-vivo functional analysis and
73 RNA sequencing revealed that CD4 and CD8 cells from patients with greater
74 abundance of CD4^{eff}PD-1+ cells displayed transcriptional and secretory features of
75 dysfunction.

76 **Conclusions:** BM infiltrating T cell subsets, specifically Treg and PD-1 expressing
77 CD4 effectors, negatively influence clinical outcomes in newly diagnosed patients.
78 Pending confirmation in larger cohorts and further mechanistic work, these immune
79 parameters may inform new risk models, and present potential targets for
80 immunotherapeutic strategies.

83

84

85

86 INTRODUCTION

87 Multiple myeloma (MM) is a common cancer of plasma cells (PC) which is
88 responsible for 2% of cancer deaths(1). Despite significant progress seen with the
89 inclusion of proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) into
90 the mainstay of treatment regimens(2), myeloma remains almost universally
91 incurable. Along with intrinsic drug sensitivities of tumour cells, and genomic drivers
92 of clonal evolution, host factors, including immunological fitness and function, likely
93 also influence clinical outcomes of treatment.

94 Accumulating evidence points towards a global immune dysregulation in MM
95 including impaired antigen presentation(3), impaired T cell effector function(4) with
96 accumulation of suppressive cell types(5,6). These mechanisms appear to converge
97 on disabling T cell driven anti tumour immunity(7) and accordingly alterations in T
98 cell phenotype and function have been consistently reported in models of MM.
99 Firstly, T regulatory cells (Tregs) suppress T cell cytotoxicity and have been reported
100 to be an important driver of disease progression(8). Secondly, there appears to be a
101 relative reduction in cytotoxic T cells relative to Tregs(8). Thirdly, checkpoint
102 proteins, such as the co-inhibitory receptor, PD-1, are reported to be expressed on T
103 cells from MM patients (9,10) with increased expression of its ligand PD-L1 on
104 tumour cells (11). Despite these reports, the influence of these alterations to T cell
105 phenotype on patient outcomes remains to be clarified. Data regarding Treg
106 numbers and relationship to clinical outcomes are conflicting (12–14) and reports of
107 increased PD-1 on T cells from MM patients have not been generally corroborated or
108 correlated to outcome(15). Reasons for these discrepancies include different assay
109 systems, examination of peripheral blood versus marrow or the use of heterogenous
110 patient cohorts. Many studies included relapsed refractory patients, where the host
111 immune system is likely to be affected by prior therapies, repeated infection and
112 advanced disease.

113 In order to resolve some of these issues, we investigated the marrow infiltrating T
114 cell populations in untreated MM patients, with focus on Tregs and co-inhibitory
115 receptors seeking to understand the influence of these recognized suppressive T cell
116 populations on the clinical outcomes of first line treatment.

117 **METHODS**

118 *Patients and controls*

119 BM aspirates were obtained from newly diagnosed (ND) MM patients with written
120 informed consent (Research ethics committee reference: 07/Q0502/17). Control BM
121 aspirates (n=15) were collected from healthy volunteers undergoing BM harvesting
122 with Anthony Nolan, and subjects undergoing bone marrow sampling who had no
123 haematological diagnosis (Supp. Table 1)(REC reference: 15/YH/0311). All BM
124 samples were collected in ethylenediamine-tetraacetic acid (EDTA) and processed
125 within 24 hours. Patients were considered to have adverse risk disease if
126 fluorescent-in-situ-hybridisation (FISH) demonstrated one of: t(4,14), t(14,16),
127 t(14,20), and del(17p).

128

129 *Isolation of mononuclear cells from bone marrow aspirates*

130 BM mononuclear cells (MNCs) were isolated by Ficoll Paque (GE Healthcare)
131 centrifugation and cryopreserved in foetal bovine serum (FBS) (Gibco) containing
132 10% DMSO (Sigma Aldrich). Aliquots were subsequently thawed for antibody
133 staining and flow cytometry, functional studies or RNA sequencing.

134

135 *Flow cytometry analysis*

136 Surface antigen staining was performed using the fluorochrome conjugated
137 antibodies CD3, CD4, PD-1, ICOS, CD25, CD33, CD11b, CD8, LAG-3, CD4, CD14,
138 CD45RA, CCR7, and fixable viability dye-e780. For intracellular staining, cells were
139 fixed/permeabilized using the FoxP3 Transcription Factor Staining Buffer Set
140 (eBioscience), then stained with Foxp3, CTLA-4, Ki-67 and GzmB. Details of all
141 antibodies are in Supp. Table 2. Data acquisition was on a BD LSR II Fortessa (BD
142 Biosciences).

143

144 *Cytokine stimulation experiments*

145 Cryopreserved BM MNCs were thawed and cultured at 0.5×10^6 cells/mL in RPMI
146 (Lonza), 20%FBS (Gibco), and 1%Penicillin/Streptomycin (Gibco) (complete
147 medium), at 37°C with soluble anti-CD3 (OKT3) and anti-CD28 (0.5 µg/ml, 15E8;
148 Miltenyi Biotec). GolgiPlug (1 µl/ml, BD Biosciences) was added for last 4 hours of
149 incubation. Cells were then stained for surface markers, CD4, CD8, CD69, and

150 fixable viability dye, washed and fixed/permeabilised for staining for intracellular
151 TNF- α , IFN- γ , IL-2, and FoxP3 (Supp. Table 2).

152

153 *RNA sequencing and analysis*

154 RNA was extracted from flow sorted CD3+CD4+ and CD3+CD8+ cells from BM
155 MNCs using ReliaPrep™ RNA Cell Miniprep System (promega). cDNA libraries were
156 prepared using the SMART-Seq v4 Ultra Low Input RNA Kit (Clontech Laboratories,
157 Inc.). Samples were sequenced on two lanes of the HiSeq 3000 instrument (Illumina,
158 San Diego, US) using a 75bp paired end run at UCL Institute of Child Health.

159 RNAseq data were processed with a modified version of the nextflow nf-core
160 RNAseq pipeline (<https://github.com/nf-core/rnaseq>). Reads were trimmed with
161 TrimGalore v0.4.1, aligned against hg19 with STAR v2.5.2a, and duplicated reads
162 were marked with Picard v2.18.9. Read counts per gene were generated with
163 featureCounts v1.6.2 and used for differential gene expression analysis. Gene set
164 enrichment analysis (GSEA) was run using Gene Ontology (GO) pathways and
165 previously reported sets of genes differentially expressed by dysfunctional CD4(16–
166 18) and CD8 T cells(19,20). Human orthologues of mouse genes were identified
167 using Ensembl and NCBI HomoloGene databases.

168

169 *Statistical analysis*

170 Progression free survival (PFS) was defined as time from start of first line therapy to
171 first progression or death (as per International Myeloma Working Group criteria(21)).
172 Flow cytometric data were analysed with FlowJo version 10 (Tree Star Inc). The
173 percentage of a cell population expressing any given marker is designated as
174 “frequency” (of that marker) within the relevant Treg, CD4 effector, or CD8
175 populations. Statistical analyses were performed with GraphPad Prism software
176 (Prism 7). P values were calculated using Mann-Whitney U test. PFS was estimated
177 using Kaplan-Meier methods with log-rank test. A multivariate Cox regression model
178 was used to evaluate the independent contribution of variables. All tests of
179 significance were 2-sided and p values ≤ 0.05 considered statistically significant.

180

181 RESULTS

182 *Patient characteristics and treatment outcomes*

183 Seventy-eight NDMM patients were identified, with median age 59 years (35-86),
184 64.1% were male (Supp Table 3). FISH defined genetic risk was available in 74
185 patients, of whom (19.2%) were adverse risk. All patients commenced active
186 treatment, most (68, 87.18%) with proteasome inhibitor regimens, and 25 (31.25%)
187 underwent autologous stem cell transplant (ASCT). Overall response rate (ORR)
188 was 87%, and 53.8% achieved complete response/very good partial response
189 (CR/VGPR). With median follow up of 22 months (1-43), median PFS was not
190 reached (NR). There was a trend for improved PFS with standard risk genetics
191 ($p=0.075$ cf high risk), ASCT ($p=0.06$), and in patients with deeper response
192 (CR/VGPR vs. rest, $p=0.09$) (Supp Fig. 1).

193

194 *BM of newly diagnosed MM patients contains high frequency of Treg cells*

195 We first examined the relative frequencies of T cell subsets in the BM of MM patients
196 (gating strategy in Fig. 1A). While the frequencies of CD3, CD4 and CD8 cells were
197 comparable to healthy donors (HD, Supp Fig. 2A), the frequency of Treg cells
198 (CD4+FoxP3+) was significantly higher in BM of MM patients (0.51% of live MNCs,
199 vs 0.07% in HD; $p<0.0001$, 3.33% of CD4+ cells vs 1.13%; $p=0.0006$) (Fig. 1B).
200 This was also the case when Treg cells were identified as CD4+CD25+FoxP3+
201 (3.41% of CD4 cells in MM BM vs 1.27% in HD; $p=0.001$) (Fig. 1B).

202 The balance between Tregs and effector T cells shapes the anti-tumour immune
203 response (22). We defined CD4 effectors (CD4^{eff}) as CD4+FoxP3- cells, and
204 observed that the CD4^{eff}:Treg ratio in MM patients was significantly lower when
205 compared with HD (20.83 vs 140.2; $p<0.0001$), this was also the case for the
206 CD8:Treg ratio (36.34 vs 170.4; $p<0.0001$) (Fig. 1C). We found no correlation
207 between Treg cells, CD4^{eff}:Treg ratio or CD8:Treg ratio with percentage of plasma
208 cells in BM (Supp Fig. 3A). Neither did we find any correlation of CD4:CD8 ratio with
209 plasma cell infiltration.

210

211 *Higher frequency of Treg cells is associated with a shorter progression free survival*

212 We sought to determine whether the presence of Treg cells in the BM of newly
213 diagnosed patients had any influence on clinical outcomes. We used PFS, a

214 common primary endpoint for studies in MM patients (23). Identifying Treg as
215 CD4+FoxP3+ cells, we observed that MM patients with a high frequency of Tregs
216 (>median, Treg^{hi}) had significantly shorter PFS when compared to MM patients with
217 low frequency of Treg (≤median, Treg^{lo}) (HR:2.91; 95%CI 1.21-7.04; p=0.021) (Fig.
218 2A). Similar findings were also seen when Tregs were identified as
219 CD4+FoxP3+CD25+ cells (p=0.022, Supp Fig. 2B). We used *surv_cutpoint* function
220 from the 'survminer' R package (<https://github.com/kassambara/survminer>) to
221 determine the optimal cut off value for Treg frequency, and ascertained this to be
222 3.31%, which is the median value.

223 Having noted that the ratios of effector cells to Treg in MM patients are low
224 compared with HD, we next examined the association with PFS. We observed that
225 patients with low CD4^{eff}:Treg ratio (≤median) had significantly shorter PFS compared
226 to high CD4^{eff}:Treg ratio (>median) (HR:4.22; 95%CI 1.79-10.15; p=0.005) (Fig. 2B).
227 There was a weaker association of CD8:Treg ratio with PFS (p=0.067) (Fig. 2B).
228 Triple colour immuno-histochemistry (IHC) was performed on BM trephine biopsies
229 to confirm presence of Tregs in representative Treg^{hi} and Treg^{lo} patients (Fig. 2C).
230 There were no associations between CD4 effectors, CD8 cells or CD4:8 ratio with
231 PFS (Supp Fig. 2B).

232

233 *Activation status of Treg cells*

234 We next examined the phenotype of marrow infiltrating Tregs, to better understand
235 their influence on clinical outcomes. We observed higher expression of CD25 on
236 Tregs from MM patients compared to HD suggesting higher level of activation of MM
237 Tregs (Fig. 3A), as CD25 expression is associated with Treg activity and suppressive
238 function(24). In this cohort of MM patients, both the abundance of CD25^{hi} cells and
239 expression intensity of CD25(MFI) was greater amongst Tregs compared to CD4
240 effectors and CD8 T cells (Fig. 3B). While there were no significant differences in
241 frequencies of PD-1, LAG-3, or CTLA-4 on Tregs from MM patients compared to HD
242 (Fig. 3A), there was a greater frequency of PD-1 and LAG-3 on Tregs from Treg^{hi}
243 patients compared to Treg^{lo} (Fig. 3C). These differences in checkpoint protein
244 expression suggest that functional as well as quantitative features of marrow
245 infiltrating Tregs in MM patients may be important (25,26). We further explored the
246 differentiation status of BM Tregs in a separate cohort of newly diagnosed MM

247 patients, observing that the majority are CD45RA- indicating that marrow Tregs in
248 these patients have an activated phenotype (Fig. 3D).

249

250 *Expression of immune checkpoint proteins on CD4 and CD8 effector cells in MM*
251 *patients*

252 Next we asked if altered Treg frequency and activation state was reflected in effector
253 T cell function in MM BM. Examining co-inhibitory and co-activation receptors on
254 CD4^{eff} and CD8 T cells, we observed that frequencies of LAG-3 and Ki-67 were
255 higher on both CD4^{eff} and CD8 T cells from MM patients compared to HD (p=0.001,
256 p=0.009, p=0.0001, p=0.0001 respectively) (Fig. 4A and 4B) with no significant
257 differences in ICOS or CTLA-4 (Fig. 4A and 4B). In addition a higher percentage of
258 CD8 T cells from MM patients expressed PD-1 (p=0.045) and the cytotoxic granule
259 GzmB compared to HD (p=0.01)(Fig. 4B). There was no correlation between the
260 frequency of any co-inhibitory or co-activation receptor on CD4^{eff} or on CD8 T cells
261 with disease burden in the BM, except for frequency of LAG-3 on CD8 T cells
262 (r=0.27, p=0.028; supp Fig. 3B).

263 Notably, we observed a positive correlation between Treg frequency and the fraction
264 of PD-1+ CD4^{eff} and CD8 cells (Supp Fig. 4), but no correlation with the frequency of
265 any other co-inhibitory or co-activation receptors. Accordingly, PD-1 expression on
266 CD4 effectors also correlated with PD-1 on CD8 cells (Supp Fig.4), and a positive
267 correlation was also noted between PD-1 expression on Treg and on CD4 effectors
268 (Supp Fig.4D). To understand the relationship between PD-1 expression and
269 differentiation status of marrow infiltrating effector cells, we further studied a similar
270 cohort of newly diagnosed MM patients. Interestingly, while terminally differentiated
271 effector memory cells re-expressing CD45RA (TEMRA) comprise a large proportion
272 of CD8 cells, this subset comprises only a minority of CD4 effectors, with the effector
273 memory (EM) subset being dominant in most patients(Supp Fig. 5A). PD-1+CD4
274 effectors were enriched for central memory (CM, CCR7+CD45RA-), and effector
275 memory (EM, CCR7-CD45RA-) cells when compared with PD-1-CD4 effectors(Supp
276 Fig. 5B).

277 Finally, the frequency of monocytic myeloid-derived suppressor cells (M-MDSCs) in
278 the BM of MM patients was higher when compared to HD (p=0.006 , Supp Fig. 6A).

279 The frequency of M-MDSCs showed only a weak correlation with CD4^{eff}PD-1+ levels
280 (Supp Fig. 6).

281

282 *Frequency of CD4^{eff}PD-1+ T cells correlates with PFS*

283 Next we examined the association of co-inhibitory receptor expression on CD4 and
284 CD8 effectors with clinical outcomes. When we divided patients into two groups
285 based on the frequency of PD-1 on CD4^{eff}, we observed that MM patients with more
286 CD4^{eff}PD-1+ cells (>median, termed CD4^{eff}PD-1^{hi}) had significantly shorter PFS
287 compared to those with less CD4^{eff}PD-1+ cells (≤median, CD4^{eff}PD-1^{lo}) (HR:3.98;
288 95%CI 1.66-9.55; p=0.007) (Fig. 4C). In contrast, there was no correlation between
289 frequency of PD-1 on CD8 T cells and PFS (Fig. 4C). There was no correlation
290 between frequency of LAG-3, ICOS or CTLA4 on either CD4^{eff} or CD8 T cells and
291 PFS (Supp Fig 7A-C). Similarly, no correlation was found between GzmB or Ki-67 or
292 on either CD4^{eff} or CD8 T cells and PFS (Supp Fig 7D-E).

293

294 *Co-inhibitory and co-activation markers on effector T cells from CD4^{eff}PD-1^{hi} patients*

295 Given the association with clinical outcomes, we examined the CD4^{eff}PD-1+ cell
296 fraction in MM in more detail. This subset co-expressed the exhaustion markers
297 LAG-3/ CTLA-4 and the terminal differentiation marker GzmB more frequently in
298 CD4^{eff}PD-1^{hi} compared with CD4^{eff}PD-1^{lo} patients (p=0.0035, p=0.046, p=0.034
299 respectively) (Fig. 4D), suggesting this subset is characterised by a dysfunctional
300 state that is more pronounced amongst CD4^{eff}PD-1^{hi} patients.

301

302 *CD4^{eff}:Treg ratio and CD4^{eff}PD-1+ cells are independent of known clinical and 303 cytogenetic predictors of PFS*

304 Having identified immune features with prognostic value, we examined both
305 CD4^{eff}:Treg ratio and CD^{eff}PD-1+ cell frequency for associations with known clinical
306 prognostic parameters. We found no association between ISS, genetic risk, ASCT,
307 or response depth with either CD4^{eff}:Treg ratio or CD^{eff}PD-1+ cells (Supp Fig. 8). A
308 multivariate Cox regression model was built including genetic risk, ASCT, ISS and
309 depth of response, and the immune features identified above. In this model,
310 CD4^{eff}:Treg ratio retained independent prognostic value, along with CD4^{eff}PD-1+
311 cells, genetic risk, ASCT, and depth of response (Fig. 5A). A risk model was built

312 including CD4^{eff}:Treg ratio, CD4^{eff}PD-1+ cells, and genetic risk, stratifying patients into
313 3 risk groups based on diagnostic features. Patients with 2 or more risk factors had
314 significantly shorter PFS (Fig. 5B).

315

316 *Effector T cells from CD4^{eff}PD^{hi} patients display transcriptional and secretory*
317 *features of dysfunction*

318 To gain mechanistic insight into the potential dysfunction of effector T cells from
319 CD4^{eff}PD-1^{hi} patients, we sorted CD4 and CD8 cells from CD4^{eff}PD-1^{hi} and
320 CD4^{eff}PD-1^{lo} patients for RNA sequencing. Gene set enrichment analysis (GSEA)
321 carried out using gene sets from previous studies of impaired CD4 function (16–18)
322 revealed that CD4 cells from CD4^{eff}PD-1^{hi} patients have transcriptional features of
323 CD4 dysfunction. Amongst three gene sets tested, all were enriched amongst genes
324 differentially expressed by CD4 cells from CD4^{eff}PD-1^{hi} patients, although only the
325 Tilstra et al. signature reached statistical significance (p <0.001, Fig. 6A). Similarly,
326 CD8 T cells from CD4^{eff}PD-1^{hi} patients also displayed transcriptional features of
327 dysfunction (Fig. 6A). We then performed GSEA to identify pathways enriched in T
328 cells from CD4^{eff}PD-1^{hi} vs. CD4^{eff}PD-1^{lo} patients. Pathways related to activation
329 downstream of T cell receptor signalling, proliferation, and regulation of apoptosis
330 were enriched in CD4 cells from CD4^{eff}PD-1^{hi} patients (Supp Fig. 9A). Similar
331 pathways of activation and proliferation were also upregulated in CD8 T cells from
332 CD4^{eff}PD-1^{hi} patients (Supp Fig. 9A), as previously described for dysfunctional CD8
333 T cells(27,28).

334 To further explore the notion that T cells from CD4^{eff}PD-1^{hi} patients are functionally
335 impaired, we next assessed cytokine secretion by stimulating whole BM MNCs with
336 anti-CD3 and anti-CD28 antibodies. We found that after 6 hours stimulation, there
337 was a trend towards higher TNF-alfa, IFN-gamma, and IL-2 production in activated
338 CD4 effectors (CD4+FoxP3-CD69+) from CD4^{eff}PD-1^{lo} patients compared to CD4
339 effectors from CD4^{eff}PD-1^{hi} patients, however only the frequency and intensity (MFI)
340 of TNF-alfa reached statistical significance (p=0.0043, Fig. 6B, p=0.0411, Supp Fig.
341 9B). A similar pattern was observed with activated CD8 T cells (CD8+CD69+) from
342 patients with CD4^{eff}PD-1^{lo}; these effectors produced more TNF-alfa compared to
343 those from CD4^{eff}PD-1^{hi} patients (p=0.026, Fig. 6B), with a trend towards higher IFN-
344 gamma and IL-2 production.

345 Collectively, these data suggest that CD4 effectors and CD8 T cells from CD4^{eff}PD-
346 1^{hi} patients display transcriptional and functional features of dysfunction that may
347 contribute to poorer outcomes.

348

349 **DISCUSSION**

350 We present data correlating the phenotype and function of BM CD4 T cell subsets at
351 diagnosis to clinical outcomes of first line treatment in a large cohort of MM patients.
352 Specifically we report for the first time that patients with a high frequency of
353 marrow infiltrating Tregs at diagnosis have poorer clinical outcomes. Beyond
354 numerical differences, high frequency of Tregs is accompanied by phenotypic
355 changes (increased PD-1 and LAG-3) suggestive of increased suppressive
356 capacity. Tregs contribute to cancer progression by directly suppressing the
357 effector T cell activity and here we also report that CD4^{eff}:Treg ratio may be
358 independently prognostic in MM. We are also the first to present data in MM
359 correlating PD-1 expression on CD4 T cells to patient outcomes, and to impaired
360 cytokine production as well as transcriptional signatures of dysfunctional CD4 and
361 CD8 cells. This supports a growing body of evidence underpinning the role of CD4 T
362 cells in the anti-tumour immune response (29), and suggests the independent
363 importance of immune dysregulation on prognosis.

364

365 Myeloma cells have been shown to promote Treg expansion in vivo(8) and in
366 vitro(30). In addition, Treg depletion improves survival in a syngeneic murine model
367 of MM(8), indicating that this is a key immunosuppressive population that facilitates
368 disease progression. Previous studies report higher levels of Tregs in PB in MM
369 patients compared to age matched controls(6,12) and in BM compared to MGUS
370 patients(14). One study reported that higher levels of Tregs in PB correlated with
371 shorter time to progression(14), but no study has systematically examined Treg
372 numbers and phenotype in the BM of newly diagnosed patients. Our is the first
373 study to examine BM infiltrating Treg at diagnosis and significantly extends these
374 earlier reports because we show for the first time that CD4^{eff}:Treg ratio in the tumour
375 environment independently associates with clinical outcomes. We also observed that
376 increased Treg numbers associated with greater frequencies of the checkpoint
377 proteins, PD-1 and LAG-3 (on Tregs), consistent with murine models of MM(8).
378 Previous work has confirmed the suppressive function of Tregs from BM of MM

379 patients(31,32), while expression levels of these checkpoint proteins is reported to
380 associate with Treg suppressive function in other cancers (25, 26, 33). Further
381 functional and molecular studies on PD-1 expressing Tregs from BM of MM patients
382 are planned, to provide mechanistic insights.

383

384 Tregs actively suppress cytolytic T cell activity(8), and the ratio of Tregs to effector
385 cells has been reported to correlate with survival outcomes(6). In this series of
386 patients the high frequency of Tregs in the BM resulted in lower effector T cell: Treg
387 ratios however only the CD4^{eff}:Treg ratio significantly correlated to PFS. In
388 comparison, there was only a trend of CD8:Treg ratio to outcome (p=0.067) which
389 challenges the prevailing view that CD8+ T cells are the dominant contributors to
390 anti-tumour immunity(34). Indeed, the anti-tumour functions of the CD4 tumour
391 compartment are increasingly recognised(29) which encompasses their helper
392 function for cytotoxic CD8+ T cells(35) as well as the ability to directly eliminate
393 tumour(36). In MM, CD4 mediated cytotoxicity of autologous tumour cells has been
394 demonstrated in vitro(37) and in a syngeneic murine myeloma model, direct CD4
395 mediated cytotoxicity was demonstrated even in the absence of tumour MHC II
396 expression(38). Moreover, in a recent in vivo autograft model, significant reduction in
397 tumour control was observed on depletion of either CD4 or CD8 T cells(39).

398

399 PD-1 is an early marker of the T cell dysfunction observed in chronic infections and
400 cancer characterised by a hierarchical loss of effector function and proliferation.
401 Classically, analysis of this dysfunctional immune state has focused on CD8 T
402 cells(40). Studies in small patient cohorts report increased PD-1 levels on CD8 cells
403 in the PB and BM of MM patients(10,41), but we are the first to show that PD-1 on
404 CD4 cells is prognostic of clinical outcomes. Despite a correlation between PD-1 on
405 CD4 effectors and CD8 cells, we did not find any association of CD8 parameters with
406 clinical outcomes. On the other hand, the CD8 compartment from CD4^{eff}PD-1^{hi}
407 patients also (as well as CD4 effectors) manifested reduced cytokine secretion and
408 transcriptional features of dysfunction, suggesting that the presence of increased
409 PD-1+CD4 effectors is indicative of a broader, pan-T cell dysfunctional phenotype.

410

411 Examining transcriptomic profiles of T cells from CD4^{eff}PD-1^{hi} patients, we observed
412 enrichment of pathways that are characteristic of T cell dysfunction. Amongst both

413 CD4 and CD8 T cells, we found enrichment of both T cell receptor (TCR) and non-
414 classical NF- κ B pathways indicative of ongoing antigen stimulation and activity of co-
415 stimulatory pathways (42) respectively. In keeping with upregulated TCR signalling,
416 we found enrichment of pathways related to transcription and cell cycle, suggestive
417 of cell activation. Whilst initial reports of T cell dysfunction in murine models of
418 chronic infection indicated a near total loss of T cell effector function (43), it is
419 increasingly clear from studies of solid malignancy that the effector potential of
420 dysfunctional T cells is reduced but not absent and active cell proliferation is a key
421 feature of this state (28,44). Consistent with previous reports of T cell dysfunction
422 (45,46) we additionally observed enrichment of metabolic pathways including
423 oxidative phosphorylation amongst both subsets and an expression profile indicative
424 of heightened sensitivity to apoptosis amongst CD4 but not CD8 T cells.

425

426 Impaired cytokine production by dysfunctional T cells has previously been reported
427 (28) and we extend this finding to BM infiltrating T cells in MM. Here we tested T cell
428 cytokine production and found this to be reduced in both CD4 and CD8 effectors
429 from CD4^{eff}PD-1^{hi} patients that reached statistical significance only for TNF- α .
430 Larger studies that take into account several variables such as stimulus, duration of
431 stimulation and cell population are required to confirm these observations. We
432 observed increased numbers of MDSCs in MM but further work is needed to explore
433 the contribution of the myeloid compartment to the immune dysfunction in untreated
434 MM marrow.

435

436 In this work, we used patient BM as opposed to peripheral blood as we wished to
437 examine the MM-driving, immune changes within the tumour microenvironment.
438 Recent in vivo MM models report differences in the immune phenotype of circulating
439 and BM infiltrating T cells(8) in disease, and indicate earlier changes within the BM
440 immune microenvironment. Similarly, a study in patient samples also reported
441 functional differences between BM and PB effector T cells(47). Additionally, we
442 found the age of patients did not correlate with CD4^{eff}:Treg ratio or CD4^{eff}PD-1 cells.
443 However, as our cohort of healthy donors were younger, comparisons with myeloma
444 patients need to be interpreted with caution. Another point to note is that a minority
445 of patients (10%) had >80% BM plasma cell infiltration, which may have amplified

446 differences in marker expression, thus our findings await confirmation in further
447 patient cohorts.

448

449 Our study suggests that immune parameters in BM of untreated MM patients may
450 inform risk of relapse, and that combining such immune features with genetic risk in
451 a new risk model identifies patients likely to have very poor outcomes. In this patient
452 cohort, we used the median frequency of Tregs (3.31%) as a cut-off value (confirmed
453 using '*survminer*'). Pending confirmation in a larger validation cohort, this measure
454 could be used to identify patients with inferior treatment outcomes who may benefit
455 from adjunctive immune-directed therapies, eg. Treg depletion strategies. Promising
456 agents include Interferon alpha/beta receptor antagonists and the use of CD25
457 antibodies optimised for depletion(22). Blockade of the PD-L1/PD-1 axis has already
458 been explored in MM(48), but in the relapsed refractory setting, and it remains to be
459 established if checkpoint blockade could overcome immune dysfunction in newly
460 diagnosed patients, eg. with high CD4 effector levels of PD-1 either as a
461 monotherapy or in combination with Treg depleting agents. The disappointing results
462 of single agent checkpoint blockade in MM has been suggested to relate to T cell
463 senescence rather than exhaustion(49). These authors however, only examined
464 CD8+ T cells, thus the question of the effect of PD-1 blockade on CD4 effector
465 function remains unanswered. Interestingly, only 3/78 patients in our cohort received
466 the IMiD lenalidomide, which acts to enhance cytokine release, augmenting T cell
467 co-stimulation signals(50). Thus, the prognostic impact of PD-1 expression on CD4
468 cells remains to be confirmed in the context of lenalidomide therapy.

469

470 In conclusion our work demonstrates that increased Treg in association with
471 dysfunctional CD4 effectors identified by high PD-1 expression correlate with
472 significantly shorter PFS in newly diagnosed MM patients. These data support the
473 importance of CD4 T cells as mediators of anti-tumor immunity in myeloma and
474 prompt further mechanistic studies to gain better understanding of the biology of
475 CD4 dysfunction and Treg function, and open up therapeutic opportunities for these
476 patients.

477 **ACKNOWLEDGEMENTS**

478 The authors would like to thank Prof David Linch (Formerly Head of the Department
479 of Haematology at University College London) for valuable comments on this
480 manuscript, and Dr Nicholas Counsell at Cancer Research UK and UCL Cancer
481 Trials Centre for statistical assistance. This study was supported by grants from the
482 Medical Research Council (MR/S001883/1), and by King Faisal Hospital and
483 Research Centre, Saudi Arabia. This work was undertaken with support from the
484 Cancer Research UK (CRUK)-UCL Centre (C416/A18088), and a Cancer
485 Immunotherapy Accelerator Award (CITA-CRUK) (C33499/A20265), at University
486 College London/University College London Hospitals, which is a National Institute for
487 Health Research Biomedical Research Centre, and a Bloodwise Research Centre of
488 Excellence. S.A.Q. is a CRUK Senior Cancer Research Fellowship
489 (C36463/A22246) and is funded by a CRUK Biotherapeutic Program Grant
490 (C36463/A20764)

689 4, and CD25 on Treg (CD4+FoxP3⁺) in Treg^{lo} (frequency of Treg ≤ median) and
690 Treg^{hi} patients (frequency of Treg >median). Mean ± SEM. *p < 0.05, **p < 0.01,
691 ****p < 0.0001, ns, not significant.

692 MM=Myeloma patients (n=78, A; n=43, B)

693 HD=Healthy donors (n=15, A; n=12, B)

694 (D) Resting (CD45RA⁺), and activated (CD45RA⁻) Tregs (CD4+FoxP3⁺) in a
695 separate cohort of newly diagnosed MM patients (n=12)(left) and representative
696 FACS plot (right) showing gating for resting and activated Tregs . ****p < 0.0001

697

698 **Figure 4. Co-activation and co-inhibitory receptors on CD4 and CD8 effector T**
699 **cells and correlation with PFS.**

700 PD-1, LAG-3, ICOS, CTLA-4, GzmB and Ki-67 expression (% positive) on (A) CD4
701 effectors and (B) CD8 T cells in HD and MM patients. .

702 (C) PFS in patients according to frequency of PD-1⁺ on CD4 effectors (left), and
703 CD8 T cells (right). PD-1^{hi} = >median, PD-1^{lo} = ≤median (D) Expression of LAG-3,

704 CTLA-4, and GzmB on PD-1⁺ CD4 effectors from CD4^{eff} PD-1^{lo} and CD4^{eff} PD-1^{hi}

705 patients (mean±SEM), and representative FACS plots of CD4^{eff}PD-1^{lo} (top) and
706 CD4^{eff}PD-1^{hi} patients (bottom).

707 *p < 0.05, **p < 0.01, ***p < 0.001, ****p < 0.0001

708

709 **Figure 5. Clinical and immune parameters influencing PFS in newly diagnosed**
710 **MM.**

711 (A) Forest plot showing hazard ratios (HR) and 95% confidence intervals (CI) for
712 each parameter, by multivariate Cox regression analysis. (B) risk model based on 3
713 baseline risk factors: CD4^{eff}:Treg ratio (≤ median), CD4^{eff}PD-1 (>median), and
714 genetic risk (High).

715 Group 1 = 0 risk factors (n=20)

716 Group 2 = 1 risk factor (n=21)

717 Group 3 = 2 or more risk factors (n=33)

718

719 **Figure 6. Effectors in CD4^{eff}PD-1^{hi} patients are transcriptionally and**
720 **functionally distinct from those in CD4^{eff}PD-1^{lo} patients**

721 (A) GSEA dot plots showing preferential expression of genes related to dysfunction
722 in CD4+ effectors (left) and CD8 cells (right) from CD4^{eff}PD-1^{hi} patients, insets refer
723 to gene sets used, NES, normalized enrichment score (B) TNF-alpha (left), IFN-
724 gamma (middle), and IL-2 (right) producing CD4 effectors (top) and CD8 effectors
725 (bottom) following stimulation with anti-CD3 and anti-CD28 for 6 hours. *p < 0.05, **p
726 < 0.01, ***p < 0.001.

Clinical Cancer Research

Marrow infiltrating regulatory T cells correlate with the presence of dysfunctional CD4+PD-1+ cells and inferior survival in patients with newly diagnosed multiple myeloma

Nouf Alrasheed, Lydia Lee, Ehsan Ghorani, et al.
